

STABILIZATION OF HIGH  $T_c$  PHASE IN BISMUTH  
CUPRATE SUPERCONDUCTOR BY LEAD DOPING

ABSTRACT

It has widely been ascertained that doping of lead in Bi:Sr:Ca:Cu:O systems promotes the growth of high  $T_c$  (110 K) phase, improves critical current density, and lowers processing temperature. A systematic investigation is undertaken in the present study to determine optimum lead content and processing conditions to achieve these.

A large number of samples with cationic compositions of  $\text{Bi}_{2-x}\text{Pb}_x\text{Sr}_2\text{Ca}_2\text{Cu}_3$  ( $x=0.2$  to  $2.0$ ) were prepared by conventional solid-state reaction technique. Samples of all compositions were annealed together at a temperature and characterized through resistance-temperature (R-T) measurements and X-ray diffraction (XRD) to determine the zero resistance temperature,  $T_c(0)$  and to identify presence of phases, respectively. The annealing temperature was varied between  $790^\circ\text{C}$  and  $880^\circ\text{C}$  to optimize processing parameters.

For  $x$  value between  $0.3$  to  $0.8$ ,  $T_c(0)$  above  $110$  K is obtained when the samples were annealed at a temperature in the range of  $855^\circ\text{C}$  to  $870^\circ\text{C}$  for  $40$  hours. The best samples showed  $T_c(0)=113$  K and critical current density of about  $200\text{A}/\text{cm}^2$ . An optimum process yielded a large volume fraction of high  $T_c$  phase as determined from intensity peaks in XRD spectra. These results were supported through magnetic susceptibility measurements on samples having high  $T_c(0)$  values. The samples showed no change in R-T characteristics on repeated thermal cycling between  $77$  K and  $300$  K, even after a few weeks of their preparation.

In brief, we report an optimum process and composition of leaded bismuth cuprate superconductor which yields nearly a high  $T_c$  single phase with highly stable superconducting properties.
